Research Article

Abstract: Garlic has long been used as a popular remedy for many ailments since a long time. The present work was undertaken to study the anticarcinogenic and antitumorigenic effects of garlic aqueous extracts in experimentally induced hepatoma in rats as well as establish a possible anticancer mechanism of garlic. The protective effects of garlic aqueous extracts against chemical induction of hepatoma as well as the curative effects of these extracts in chemically induced hepatoma rats were studied. It is evident from the results that garlic aqueous extracts gives protection against chemical hepatoma induction. There is a considerable improvement seen in chemical induced hepatoma rats given garlic aqueous extracts. These protective as well as curative effects of garlic aqueous extracts may be due to its principal sulfur compound diallyl disulfide. The principal organosulphur compound of garlic is known to possess many clinical beneficial effects, but its overuse or abuse has been reported to cause certain harmful side effects due to its possible metabolite acrolein. It was thought that the disulphide nature of diallyl disulphide is responsible for its anticarcinogenic and antitumorigenic effects.

Keywords: Garlic, Hepatoma, Nitroso R salt, diallyl disulfide, lipid profile.

Introduction

Garlic is commonly used as a spicy food item in all parts of the world. It has long been as a popular remedy for a variety of ailments. Epidemiological as well as laboratory studies have shown that garlic consumption reduces certain cancer incidences in the stomach, colon, mammary, cervical etc. One of the mechanisms of garlic’s cancer prevention effect may be by preventing the formation of nitroso compounds as garlic is known to prevent formation of N-nitroso proline in humans. By this mechanism the sulfhydryl compounds of garlic block the conversion of nitrites into nitrosamines, which are a group of the most potent carcinogens in my opinion diallyl disulfides can also block nitrosamine formation through a similar mechanism. Garlic has been shown to metabolized into N-acetyl-s-allyl cysteine, allylmercaptan, diallyl disulfide, diallyl sulfide, diallyl sulfoxide, diallyl-sulfone and allyl methyl sulfide. Garlic has been thought to bring about its anticarcinogenic effect through a number of mechanisms, such as the scavenging of free radicals, increasing glutathione levels, increasing the activities of enzymes such as glutathione s-transferase, catalase, inhibition of cytochrome p4502E1, DNA repair mechanisms, preventing of chromosomal damage¹. The Combination chemoprevention by dietary agents is a promising approach toward cancer control. Many dietary agents are known to prevent experimental Mutagenesis and carcinogenesis by modulating xenobiotic-metabolizing enzymes. The present study evaluated the combinatorial chemopreventive effects of tomato and garlic on hamster buccal pouch carcinogenesis induced by 7, 12-dimethyl benz (a) anthracene (DMBA)². There was no credible evidence to support a relation between garlic intake and a reduced risk of gastric, breast, lung or endometrial cancer, very limited evidence supported a relation between garlic consumption and reduced risk of colon, prostrate, esophageal, larynx, oral, ovary or renal cell cancer³. Garlic and garlic derived compounds reduce the development of mammary cancer in animals and suppress the growth of human- breast cancer cells in culture. Oil soluble compounds derived from garlic, such as diallyl disulphide (DADS), are more effective than water soluble compounds in suppressing breast cancer. Mechanisms of action include the activation of metabolizing enzymes that detoxify carcinogens, the suppression of DNA adduct formation, the inhibition of the production of reactive oxygen species, the regulation of cell-cycle arrest and the induction of apoptosis⁴.

Materials and methods

The present work was undertaken to study the anticarcinogenic and antitumorigenic effects of garlic
extracts in experimentally induced hepatoma in rats, as well as to establish a possible anticancer mechanism of garlic. This work was conducted at Department of Biochemistry, Animal house of Dr. B.R. Ambedkar Medical College upon approval of the committee of ethics in animal experimentation (132/1999/CPCSEA).

**Experimental animals**

Inbred adult male albino rats of 3-4 months old, weighing 100-150 g were used for the study. The rats were obtained from the stock inbred colony which was maintained by matings of brothers and sisters. The rats were maintained on dry pellets of laboratory feed (Amrut rat feed, Navamaharashtra Chakan Oil Mills Ltd., Pune) and tap water.

**Preparation of garlic aqueous extracts (GAE)**

One part of fresh garlic bulbs were crushed with one part of water (w/v) in warring blender. It was filtered through a gauze cloth. One ml of this filtrate was considered equivalent to an aqueous extract of 500 mg garlic. This was prepared fresh each time. An optimum dose of 3 g/kg body weight was employed in this study. This 3 g optimum dosage was arrived at as a result of previous experiments conducted in our lab.

**Experimental groups**

For the present study rats were divided into 4 groups, consisting of 6 rats in each group.

**Group 1:** Normal group- consisting of 6 normal rats maintained on laboratory diet ad libitum.

**Group 2:** Control group

Hepatoma in rats was induced by Nitroso-R-Salt instead of diethyl nitrosamine (DEN) \(^5\). Consisting of 6 male albino rats, maintained on lab diet ad libitum and given an initial dose of CCI\(_4\) (3mg/kg body weight) was given. On the 7\(^{th}\) day a high dose of Nitroso-R-Salt (300 mg/kg body weight) was given. On the 14\(^{th}\) day a second dose of CCI\(_4\) (3 mg/kg body weight) was given. Then the rats were maintained on a diet containing phenobarbital (0.05%) for further 16 weeks.

**Group 3:** AEG Protective group

Consisting of 6 albino rats, maintained on lab diet ad libitum and given 3g aqueous extract of garlic (AEG) as 30 ml warm aqueous solution/kg body weight using gastric tube daily for 3 days. On the 4\(^{th}\) day an initial dose of CCI\(_4\) (3 mg/kg body weight) was given. On the 7\(^{th}\) day a high dose of Nitroso-R-Salt (300 mg/kg body weight) was given. On the 14\(^{th}\) day a second dose of CCI\(_4\) (3 mg/kg body weight) was given. Then the rats were maintained on a diet containing phenobarbital (0.05%) for further 16 weeks. All the rats of this group were given daily from 4\(^{th}\) day till the end aqueous extract of garlic 3 g/kg body weight.

**Group 4:** AEG Curative group

Consisting of 6 albino rats, maintained on lab diet ad libitum and given an initial dose of CCI\(_4\) (3mg/kg body weight) was given. On the 7\(^{th}\) day a high dose of Nitroso-R-salt (300 mg/kg body weight) was given. On the 14\(^{th}\) day a second dose of CCI\(_4\) (3 mg/kg body weight) was given. Then the rats were maintained on a diet containing phenobarbital (0.05%) for further 16 weeks. All the rats of this group (group 4) were given daily from 16 weeks till the 32 weeks 3g aqueous extract of garlic (AEG) as 30 ml warm aqueous solution / kg body weight using gastric tube daily for 32 weeks. Blood from rats was collected with heparin as anticoagulant after the stipulated time by cutting the jugular vein with a sharp blade. Blood samples were centrifuged at 1500 rpm for 10 minutes. The plasma samples were used for the estimations of glucose \(^6\), uric acid \(^7\), total proteins (TP) \(^8\), albumin \(^9\), total lipids(TL) \(^10\), total cholesterol(TC) \(^11\), triacyl-glycerols (TAG) \(^12\), phospholipids (PL) \(^13\), aspartate transaminase (AST) \(^14\), alanine transaminase (ALT) \(^15\), free fatty acids (FFA) \(^16\), total aminoacid nitrogen (total AAN) \(^17\) and vitamin C (Vit C) \(^18\). The liver was removed to ice cold containers and processed immediately. A part of the liver tissue was homogenized with chloroform- methanol (1:1 v/v) and the extracts were used for the estimations of lipid parameters TL \(^10\), TC \(^11\), TAG \(^12\) and PL \(^13\). Another part of the liver tissue was homogenized with phosphate buffer (pH 7.4) and the extracts were used for the estimations of AST \(^14\), ALT \(^15\) and total –SH groups \(^19\). A third part of the liver tissue was homogenized with 5% TCA and the extracts were used for the estimation of thiobarbituric acid reactive substance (TBARS) \(^20\). A fourth part of the liver tissue was homogenized with 10% TCA. The extracts were used for the estimations of total DNA \(^21\) and DNA damage \(^20\). The DNA damage was estimated by estimating TBARS levels of isolated DNA. A fifth part of the liver tissue was immediately put into buffered formalin for histopathological studies.

**Statistical Analysis**

Data obtained were analyzed comparing the results of groups using students ‘t’ test Probability values less than 0.02 were considered as significant.

**Results**

Results obtained in the present study are given in tables 1 to 2 & Figs. 1-4. Figures 1 to 4 shows the cross section of liver in normal rats, garlic aqueous extract treated chemically induced hepatoma rats and experimentally hepatoma induced rats given GAE respectively. Figures 1 & 2 show normal liver tissue and malignant liver tissue respectively. As seen from the figures, a significant protection against experimental induced hepatoma is seen.
in rats treated with GAE prior to cancer induction (Fig 3), whereas a significant. Control of cancer is seen in hepatoma rats given GAE orally (Fig 4).

Table 1 gives the levels of TAG, PL, AST, ALT & FFA are elevated in control group as compared to normal group, whereas the levels of PL, AST & ALT are raised in protective & curative groups as compared to control group, but TAG & FFA are decreased in these groups as compared to control group.

Table 2 gives the levels of AST, ALT, TL, PL, TBARS, DNA damage and total DNA are raised in control group as compared to normal group, whereas these parameters except AST, ALT, PL total – SH groups are decreased in both protective as well as curative groups as compared to control group.

**Discussion and Conclusion**

Feeding GAE (3 gm/kg body weight) daily for seven days prior to induction of hepatoma gives a fair protection as seen from Fig 3. This hepatoma protective effects as garlic extracts may be due to its sulfur compounds-thiols and disulfides, these sulfur compounds may undergo an exchange reaction with fatty acid synthase, HMGCoA reductase, glycerol-3-phosphate dehydrogenate and probably with nucleic acid ligase decreases fatty acid synthesis, cholesterol synthesis, triacyl glycerol synthesis and nucleic acid production respectively, thereby causing a decrease in these levels which is evident from tables 1 to 2.

The principal disulfide present in garlic is diallyl disulfide (DADS)\(^{25}\). This may be metabolized as any disulfide in the body to give rise to allyl thiols which may be involved in maintenance of glutathione levels which is evident from tables 1 to 2. Such a metabolic degradation of DADS consumes NADPH resulting in a decrease of cellular NADPH. This may result in decreased fatty acid, cholesterol and triacyl glycerol synthesis. The decrease in these in part may be due to direct inhibition of synthesis by allin, alliin and by DADS of garlic extracts\(^{25}\).
